Stem cells are the body's raw materials cells from which all other cells with specialized functions are generated. Under the right conditions in the body or a laboratory, stem cells divide to form more cells called daughter cells. These daughter cells either become new stem cells (self-renewal) or become specialized cells (differentiation) with a more specific function, such as blood cells, brain cells, heart muscle cells or bone cells. No other cell in the body has the natural ability to generate new cell types. Stem cells are divided into two major classes; pluripotent and multipotent. Pluripotent stem cells are replicating cells, which are derived from the embryo or fetal tissues. The pluripotent stem cells facilitate the development of cells and tissues in three primary germ layers such as mesoderm, ectoderm, and endoderm.
