Change in packaging techniques for alkaline batteries is the latest trend in the global alkaline batteries market. Alkaline batteries battery manufacturers are changing their battery packaging techniques to offer more convenience to their customers. In the past, alkaline batteries were made with complex sealing systems and thick steel outer cases, and end caps. A unique method was developed that allowed manufacturers to use thinner packaging materials and more

efficient seals. More room was created for active materials within a given standard cell size, and that increased capacity. For instance, Panasonic Corp. has launched their alkaline batteries in packs of 10, believing that the new package size was especially practical for distributors since it allows more exact calculations.

Alkaline batteries are composed of zinc and manganese dioxide as electrodes. The positive electrode (cathode) in an alkaline battery is based on manganese (IV) oxide and the negative electrode (anode) is based on zinc. Power in the battery is produced through two chemical reactions at the positive and negative electrodes. Manganese (IV) oxide is converted into manganese (III) oxide and hydroxyl ions at the positive electrode, while zinc reacts with the hydroxyl ions to release the electrons that power the circuit at the negative electrode.
