Vertebroplasty and kyphoplasty are minimally invasive surgical procedures used to treat compression fractures of the spine, which can be caused by osteoporosis or other conditions that weaken the bones. Vertebroplasty involves the injection of a special type of cement (bone cement) into the fractured vertebra, which stabilizes the bone and provides pain relief. The procedure is typically performed under local anesthesia with the guidance of X-ray or CT imaging.

Kyphoplasty is similar to vertebroplasty, but it involves the use of a balloon to create a space in

the compressed vertebral body before the bone cement is injected. The balloon is inflated to restore the height of the collapsed vertebra and create a cavity where the cement can be injected. This technique can restore the shape of the vertebral body and can be useful in reducing spinal deformity.
