Enzyme inhibitors are molecules or compounds that selectively bind to an enzyme, thereby reducing or completely inhibiting its activity. Enzymes are proteins that play essential roles in catalyzing biochemical reactions in living organisms. They facilitate the conversion of substrates into products by lowering the activation energy required for the reaction to occur. Enzyme inhibitors interfere with this catalytic process by binding to the enzyme, either reversibly or irreversibly, and disrupting its normal function.

There are different types of enzyme inhibitors, including competitive inhibitors, non-competitive inhibitors, and uncompetitive inhibitors. Competitive inhibitors compete with the substrate for the active site of the enzyme, effectively reducing the binding of the substrate and slowing down

the catalytic reaction. Non-competitive inhibitors, on the other hand, bind to a different site on the enzyme, causing a conformational change that hinders the enzyme-substrate interaction. Uncompetitive inhibitors bind to the enzyme-substrate complex, preventing the release of the product. By modulating enzyme activity, inhibitors can regulate metabolic pathways, control physiological processes, and serve as potential therapeutic targets for drug development.
