Non-alcoholic steatohepatitis (NASH) is a type of liver inflammation and damage caused by a build-up of fat in the liver. NASH biomarkers are used as diagnostic tools to assess the severity of non-alcoholic steatohepatitis and to assess liver damage. This damages the liver cells and inflames the liver, which can result in cirrhosis (liver scarring) and liver failure. Biomarkers refer to a particular quality that can be tested to reveal pathogenic processes, healthy biological processes, or reactions to exposure or treatment.
