Bifurcation lesions refer to a coronary artery constriction that occurs next to or involves the origin of a vital side branch one does not want to lose. It occurs when plaque deposits accumulate, and the artery becomes too small for adequate blood flow to your heart.

The main types of bifurcation lesions are one-stent and two-stent. One-stent bifurcation lesions refer to a procedure where the side branch is provisionally stented if the intervention is required owing to clinical complaints, angiographic results, or other adjunctive variables. The main branch is stented first in this approach. The bifurcation angle is determined by the internal angle between the main and side branches. These types of bifurcation lesions are applied in coronary and peripheral vascular.
