## Hemophagocytic Lymphohistiocytosis Overview

Hemophagocytic lymphohistiocytosis (HLH) is a rare and life-threatening condition caused by an excessively active and abnormal immune system response, which normally defends the body against foreign invaders. HLH can arise from various underlying causes and is known by different names. Familial hemophagocytic lymphohistiocytosis (FHL) refers to genetic forms resulting from mutations in specific genes.

HLH can be broadly categorized into primary (genetic) and secondary (acquired) forms, both resulting from an ineffective and abnormal immune response to a triggering stimulus. Diagnosis involves identifying characteristic symptoms, a thorough patient history, clinical evaluation, and specialized tests.

Treatment for HLH is tailored to address individual-specific symptoms. Gamifant (emapalumab) has been approved for treating pediatric and adult patients with primary HLH who have refractory, recurrent, or progressive disease or cannot tolerate conventional HLH therapy.
