

AGIS' C5ISR Software Assists U.S. Stealth mode Operations

How satellite owner identification enhances defense capabilities

JUPITER, FL, UNITED STATES, December 16, 2024 /EINPresswire.com/ -- Satellites, UAV's, and Long Range missiles have changed the nature of warfare for both offensive and defensive operations. In today's warfare tempo, a soldier's survival often hinges upon the ability to [remain unseen and undetected](#) amid relentless surveillance of overhead

satellites and drones. The phrase "to be seen is to die" captures the essence of stealth and the importance of remaining undetected in military operations because high stakes are involved in combat situations where visibility can mean threats to survivability.

The phrase "to be seen is to die" captures the essence of stealth and the importance of remaining undetected”

Malcolm K. Beyer, Jr. CEO

Modern satellites possess capabilities that allow the capture of high-resolution images, the detection of heat and communication signatures. These allow the monitoring of troop movements with unprecedented precision. Since satellite and UAVs can relay intelligence rapidly, even a moment of exposure can lead to devastating consequences from airstrikes and long-range fires,

Being careful to remember that to be seen is to die, warfighters soon understand that concealment is an essential skill — one that determines life or death, and success or failure. Understanding the importance of strategy, deception, and the element of surprise in military operations, AGIS has jumped in by building a capability for ground troops to identify enemy satellites and drones in real time, and AGIS has integrated this capability into its COP software.

Within its [CJADC2 C5ISR](#) system, the AGIS COP assists in shielding soldiers from overhead observation by providing information on a [satellite's location and a satellite's country of](#)

[ownership](#). The AGIS C5ISR software can inform soldiers if and when a hostile country's satellites are passing or about to pass over their ship and ground positions. AGIS provides real time tracking done with software tools that use the specific orbit to predict when and where a satellite owned by a hostile country will be visible from any given location on Earth, and thus the dates, times, and directions for each of their satellites' passes. This early warning of possible surveillance or discovery will enable our forces to take necessary precautions, such as altering positions, avoiding GPS use, or modifying communications to avoid detection. Being seen or detected can lead to failure, while stealth and making unexpected maneuvers can lead to victory.

AGIS provides this capability as military operations become increasingly reliant on space-based assets and the importance of accurate, real-time detection, identifications, and visualizations continue to grow, making this software feature an essential component for future military readiness.
